A three-phase diode rectifier converts a three-phase AC voltage at the input to a DC voltage at the output. To show the working principle of the circuit the source and load inductances (L_s and L_d) are neglected for simplicity. The DC voltage is divided into six segments within one fundamental source period that corresponds to the different line-to-line source voltage combinations (V_{LL}).

Phase B starts at 0 at 120 degrees and Phase C starts at 0 at 240 degrees. A full wave rectifier produces the absolute value of each phase, and then takes the MAX of the three rectified phases. The net effect is that of the three, phase A is the max between 60 and 120 degrees and again between 240 and 300 degrees, and so on for the other two.

A three phase full wave diode rectifier with purely resistive load is shown below. The AC voltage supply is 110 V line to line and 50 Hz frequency. The waveform of the voltage across the load is shown in black in the figure below. V_m -phase is the maximum of phase voltage. The minimum of the voltage across the load is $1.5 V_m$ -phase.

When there is need of rectifying three phase AC, we use a three phase rectifier. Basically a rectifier eliminates the negative cycle of AC, so by principle we can get a much better result if we do rectification another time. There are two basic types of three phase rectifiers, 6 pulse rectifiers and 12 pulse rectifiers.

In every house the power supply provided by the government is three phase Alternating (AC) but most of our devices like laptops and mobile phones uses Direct voltage (DC voltage) for their charging. Hence a three phase rectifier is now a days used in almost every house and is a very common device to be used.

Simulation and design of Three phase Rectifier in Simulink ...

Three-phase controlled rectifiers have a wide range of applications, from small rectifiers to large High Voltage Direct Current (HVDC) transmission systems. They are used for electro-chemical process, many kinds of motor drives, traction equipment, controlled power supplies, and many other applications. From the point of view of the commutation process, they can be classified in two important categories: Line Commutated Controlled Rectifiers (Thyristor Rectifiers), and Force Commutated PWM.

With single phase, the calculation is a bit iffy, because the reservoir capacitor makes the rectifiers draw very high peak currents. With three phase like you have, the situation is much easier, as with no reservoir capacitor, the current is ripply rather than very peaky, and is actually calculable.
